Caption

On the west coast of Greenland, 250 km north of the Arctic Circle, in the disko bay many icebergs drift into the fjord and gradually melt into the ocean. These icebergs come from Jakobshavn Glacier (Sermeq Kujalleq in Greenlandic) listed as World Heritage Site since 2004. The glacier is one of the largest icebergs in the northern hemisphere suppliers. . This results in an annual production of 20 billion tonnes of icebergs (which represents the amount of fresh water used annually in France).
